

# Signalled and unsignalled delayed reinforcement

Effects of *d*-amphetamine,  
clordiazepoxide,  $\alpha$ -flupenthixol, and  
behavioural manipulations

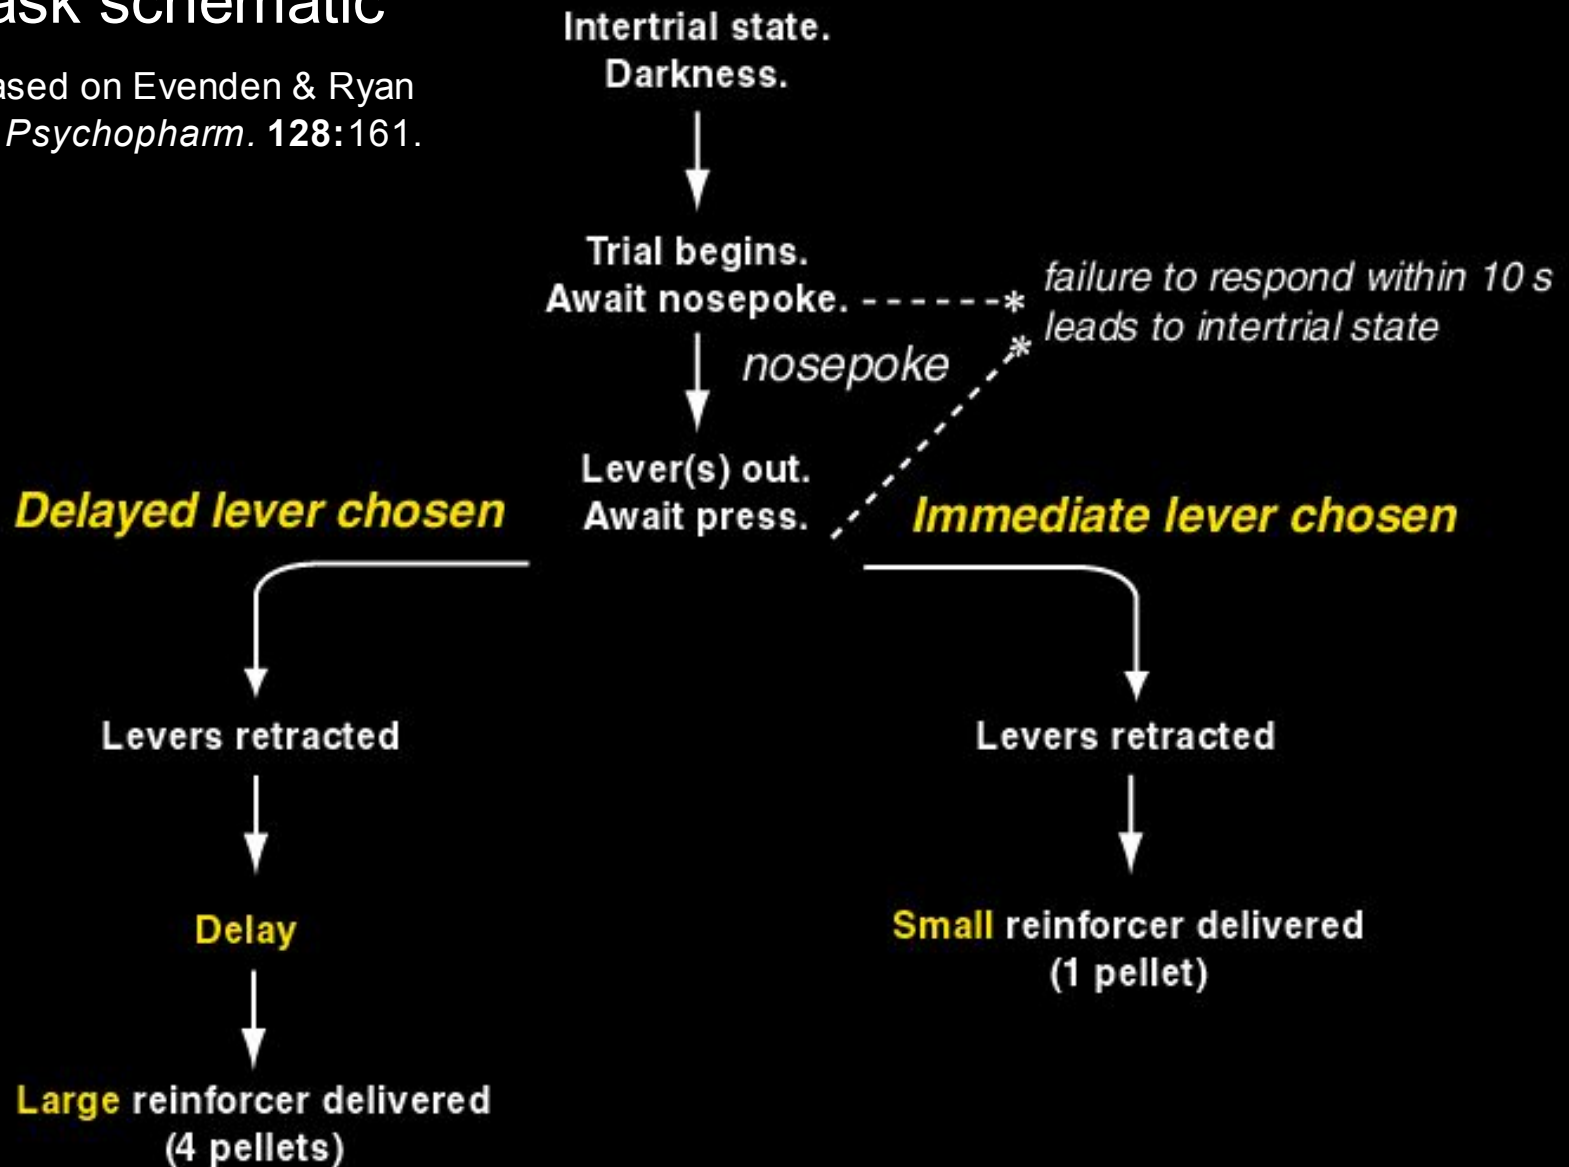

*Rudolf Cardinal, Barry Everitt, Trevor Robbins*

*University of Cambridge, UK*

*Presented at EBPS/BPS, Boston '99*

# 1. Task schematic

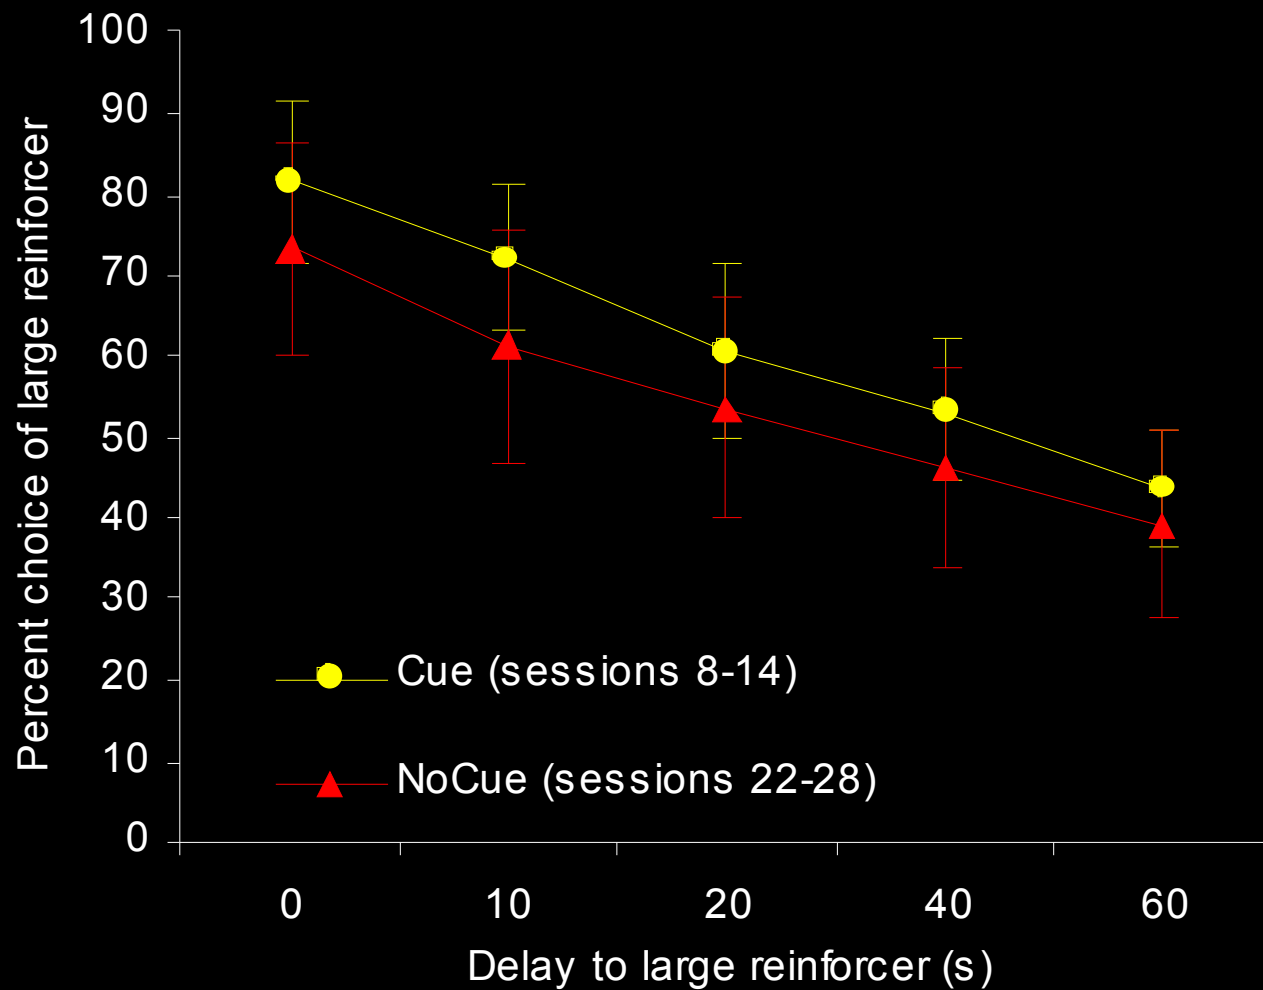

Task based on Evenden & Ryan (1996), *Psychopharm.* **128**:161.

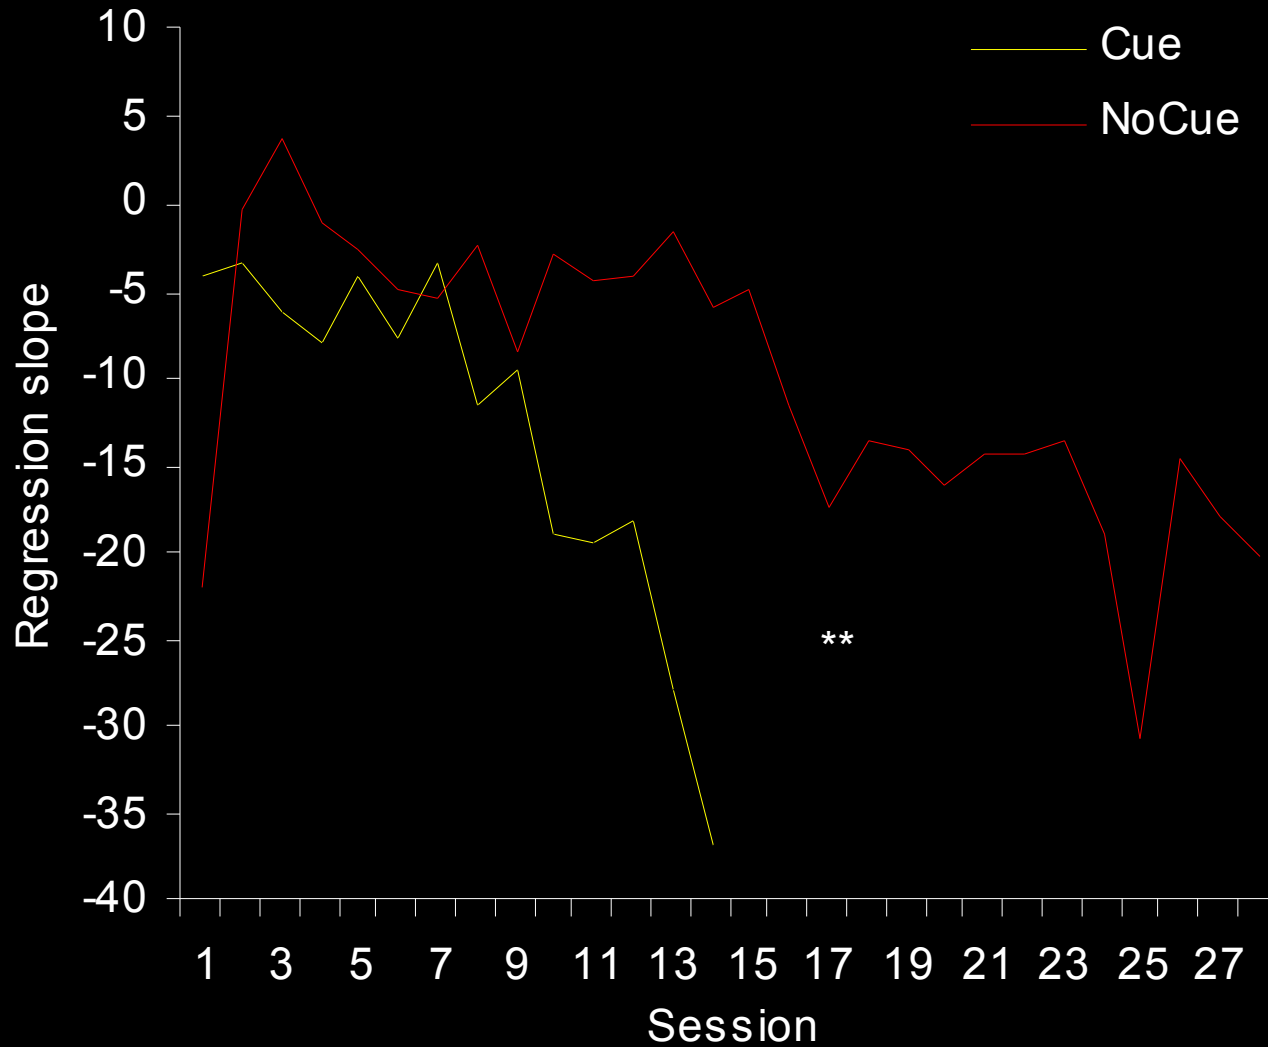

## 2. Signalled or unsignalled delayed reinforcement

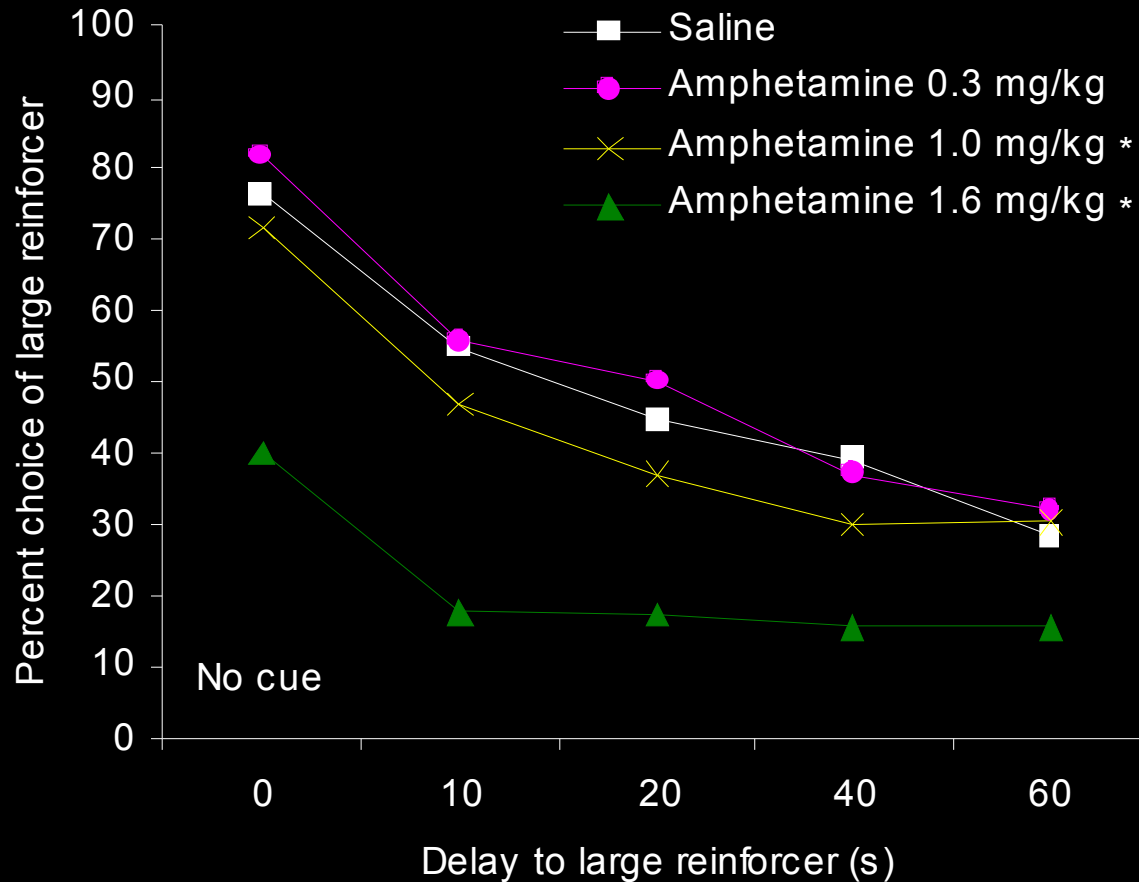

### 3. Cues do not affect baseline choice

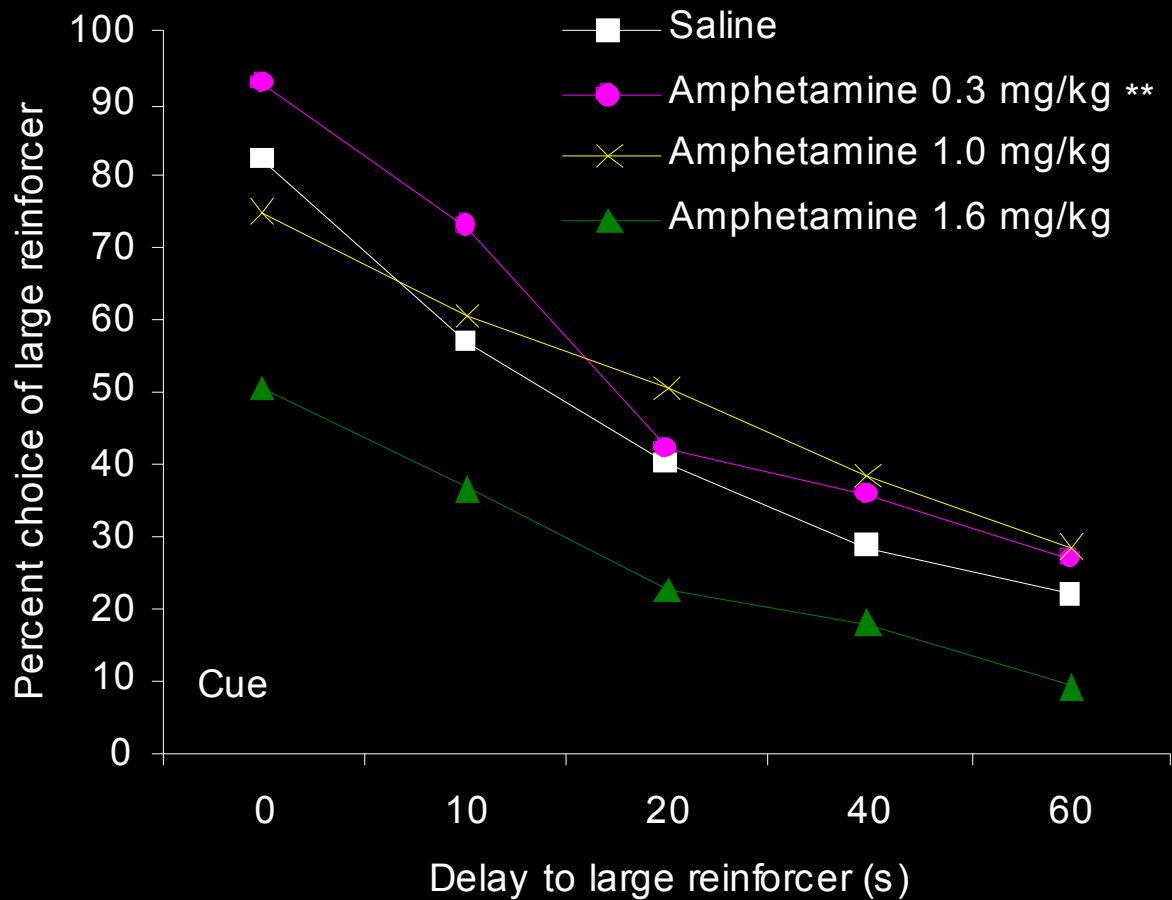

## 4. Cues speed acquisition of delay sensitivity

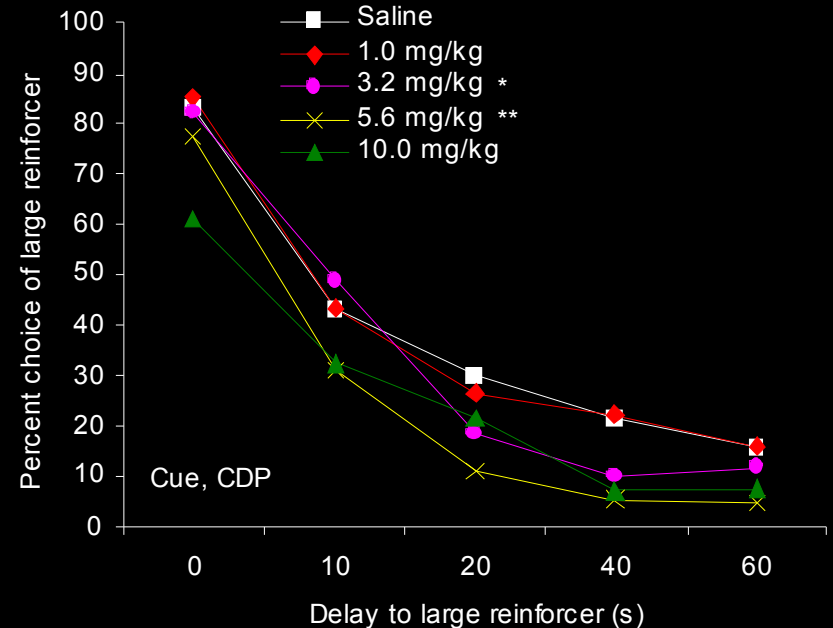

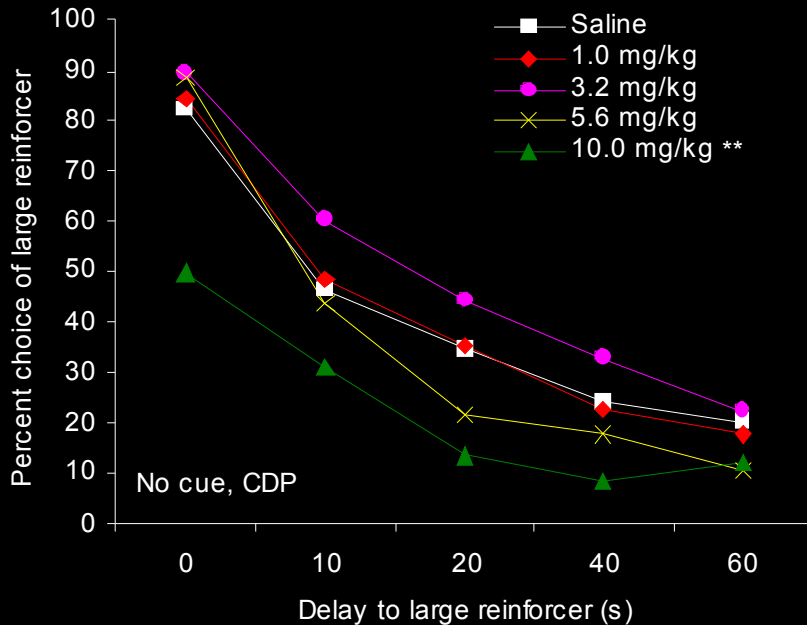

5. In the absence of cues, amphetamine *decreases* preference for the larger, delayed reward (increases “impulsivity”)

## 6. In the presence of the cue, amphetamine *increases* preference for the larger, delayed reward

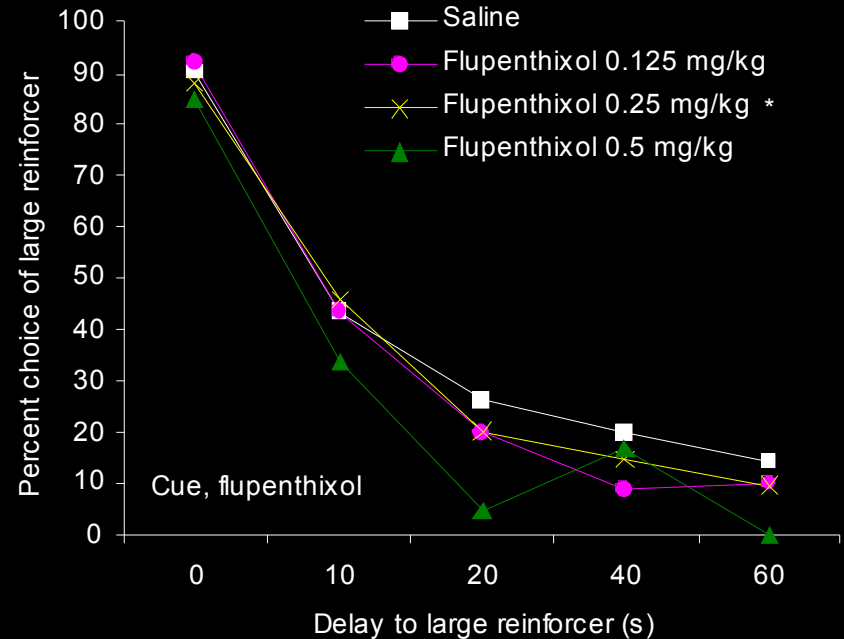

# 7. Chlordiazepoxide

The effects of chlordiazepoxide were not altered by the cue. Its most consistent effect was to *decrease* preference for the large, delayed reward.

## 8. $\alpha$ -Flupenthixol

Flupenthixol *decreased* preference for the large, delayed reward, irrespective of the cue. Thus its effects in the Cue condition were opposite to those of amphetamine.

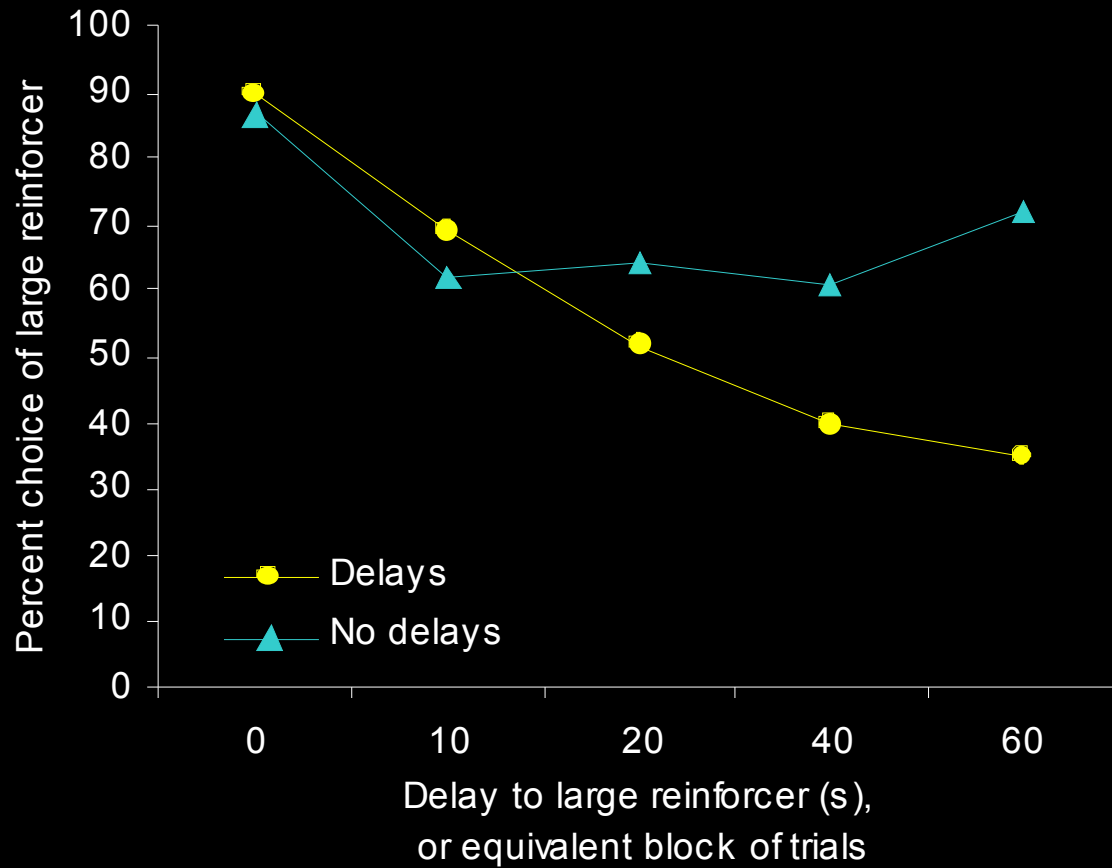

## 9. Flupenthixol abolishes the ability of the cue to sustain nosepoking during the delay

## 10. Conclusions

- Signalling a delay to reinforcement can have important effects on choice behaviour.
- Cues present during the delay have the potential to become conditioned reinforcers.
- Dopaminergic agonists are known to potentiate the effects of conditioned reinforcement.
- Amphetamine interacts with the presence of a cue in this task. There is a cue-dependent effect to *increase* preference for the larger, delayed reward, and a cue-independent effect to *decrease* that preference.
- Chlordiazepoxide does not interact with the cue, and generally *decreases* choice of the delayed reward.
- ∇  $\alpha$ -Flupenthixol *decreases* choice of the delayed reward. It also impairs the cue's control over approach behaviour.
- These results are consistent with the conditioned reinforcement hypothesis.

# Supplement 1. Rats remain sensitive to delay: effect of setting all delays to zero

## Supplement 2. Rats remain sensitive to delay: preference alters when the delay sequence is reversed
